Q1: Internationalization is a generally translate a language, date etc. to another one without recompile program by using outside source code and retrieved dynamically. Localization need to add locale-specific components and translating text, sound images based on local culture and marketing strategy

Q2: Internationalization save works for coders that they do not need to recompile program and also it make more users can use that program. Such as Linux system, it is an open source software and translate to many languages that all programmers can develop it. Localization makes specific components for different language users based on what they need. Such as Apple Store has very different app lists for China and U.S. users, also the prices of Apple products on the website of Apple are not easily translate currency. The products in China is more expensive than U.S even most of Apple factories are in China.
